Introduction

Library Management System is a Binary Search Tree based program, where the books will be stored in a binary search tree based on a specific key(ex.: book title). Each node could represent a book and contains information of the book (i.e. title, author, etc). By this software students can issue books and the admin or librarian can update/delete the record of books kept in the library.

Features

Librarian login

- Add book
- Delete book
- Update book
- Print all books(inorder-traversal)

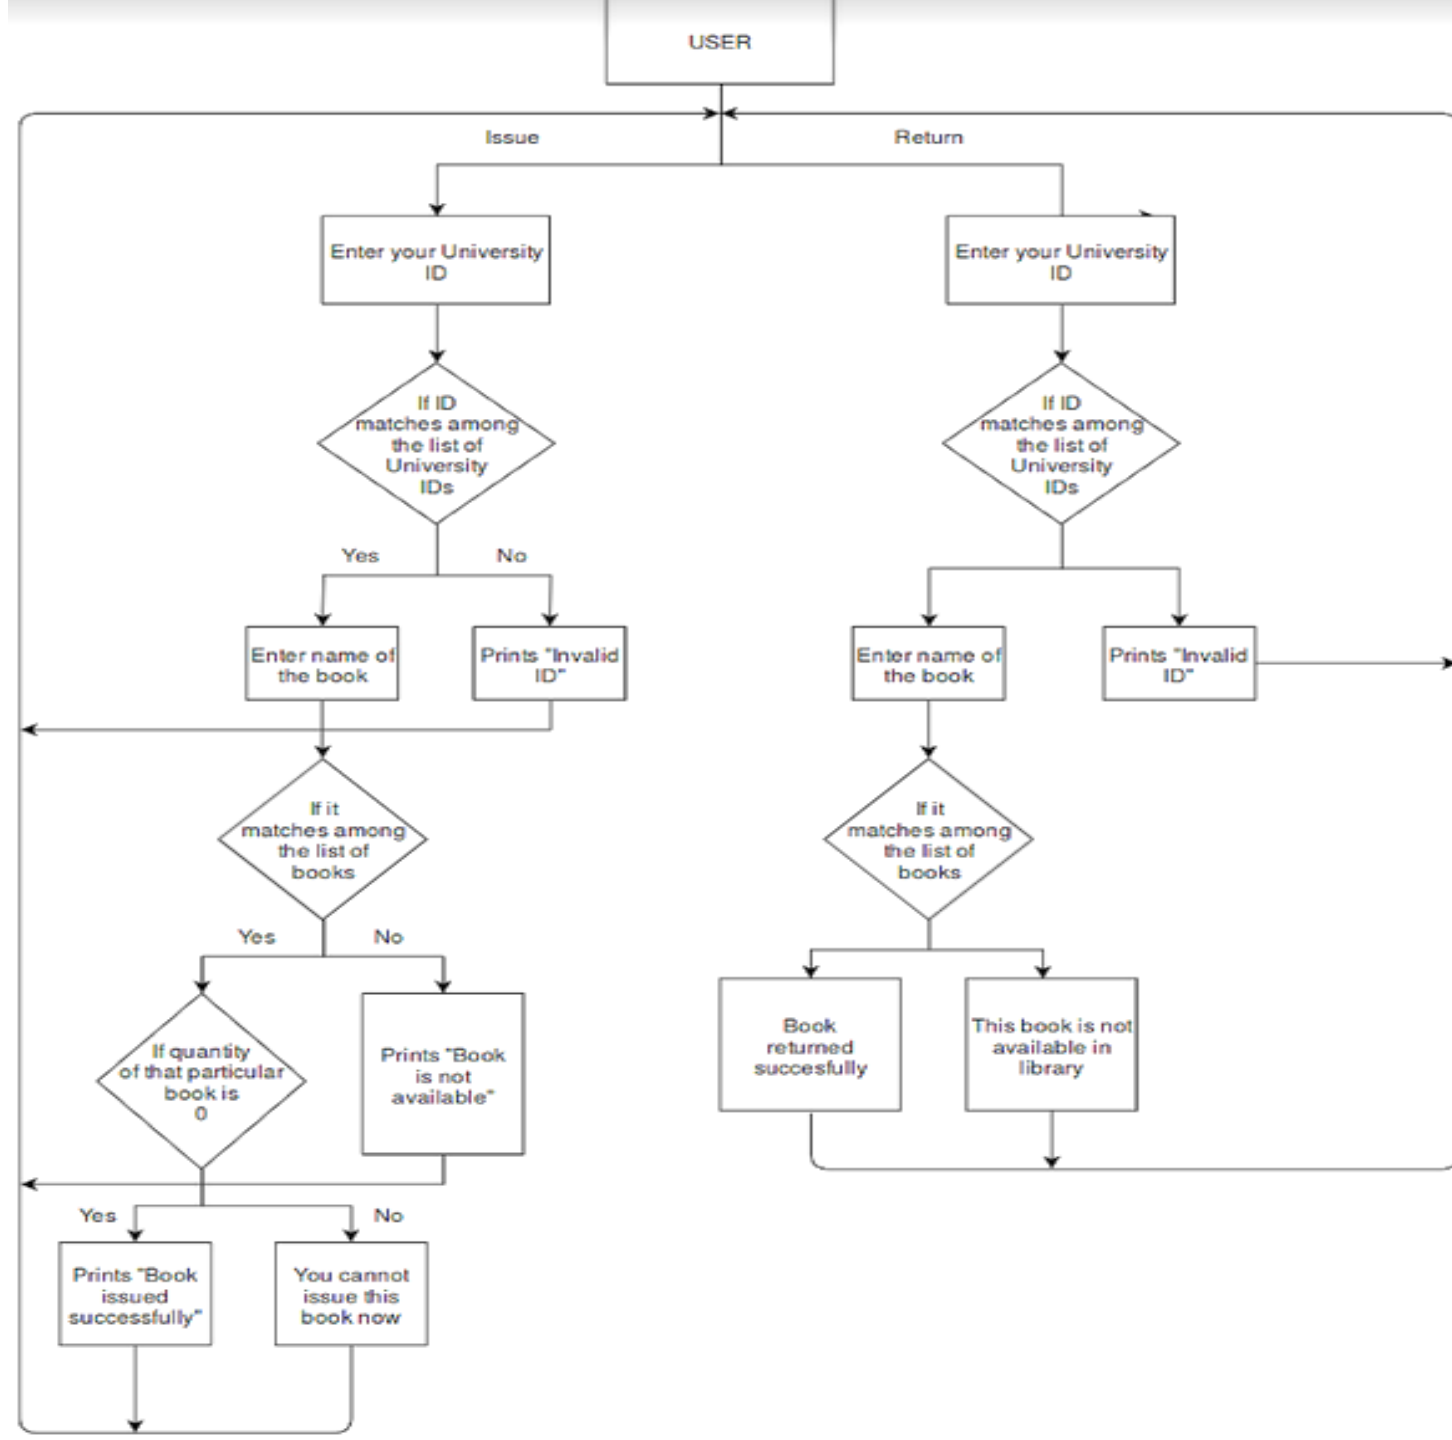

User login

- Issue book
- Return book

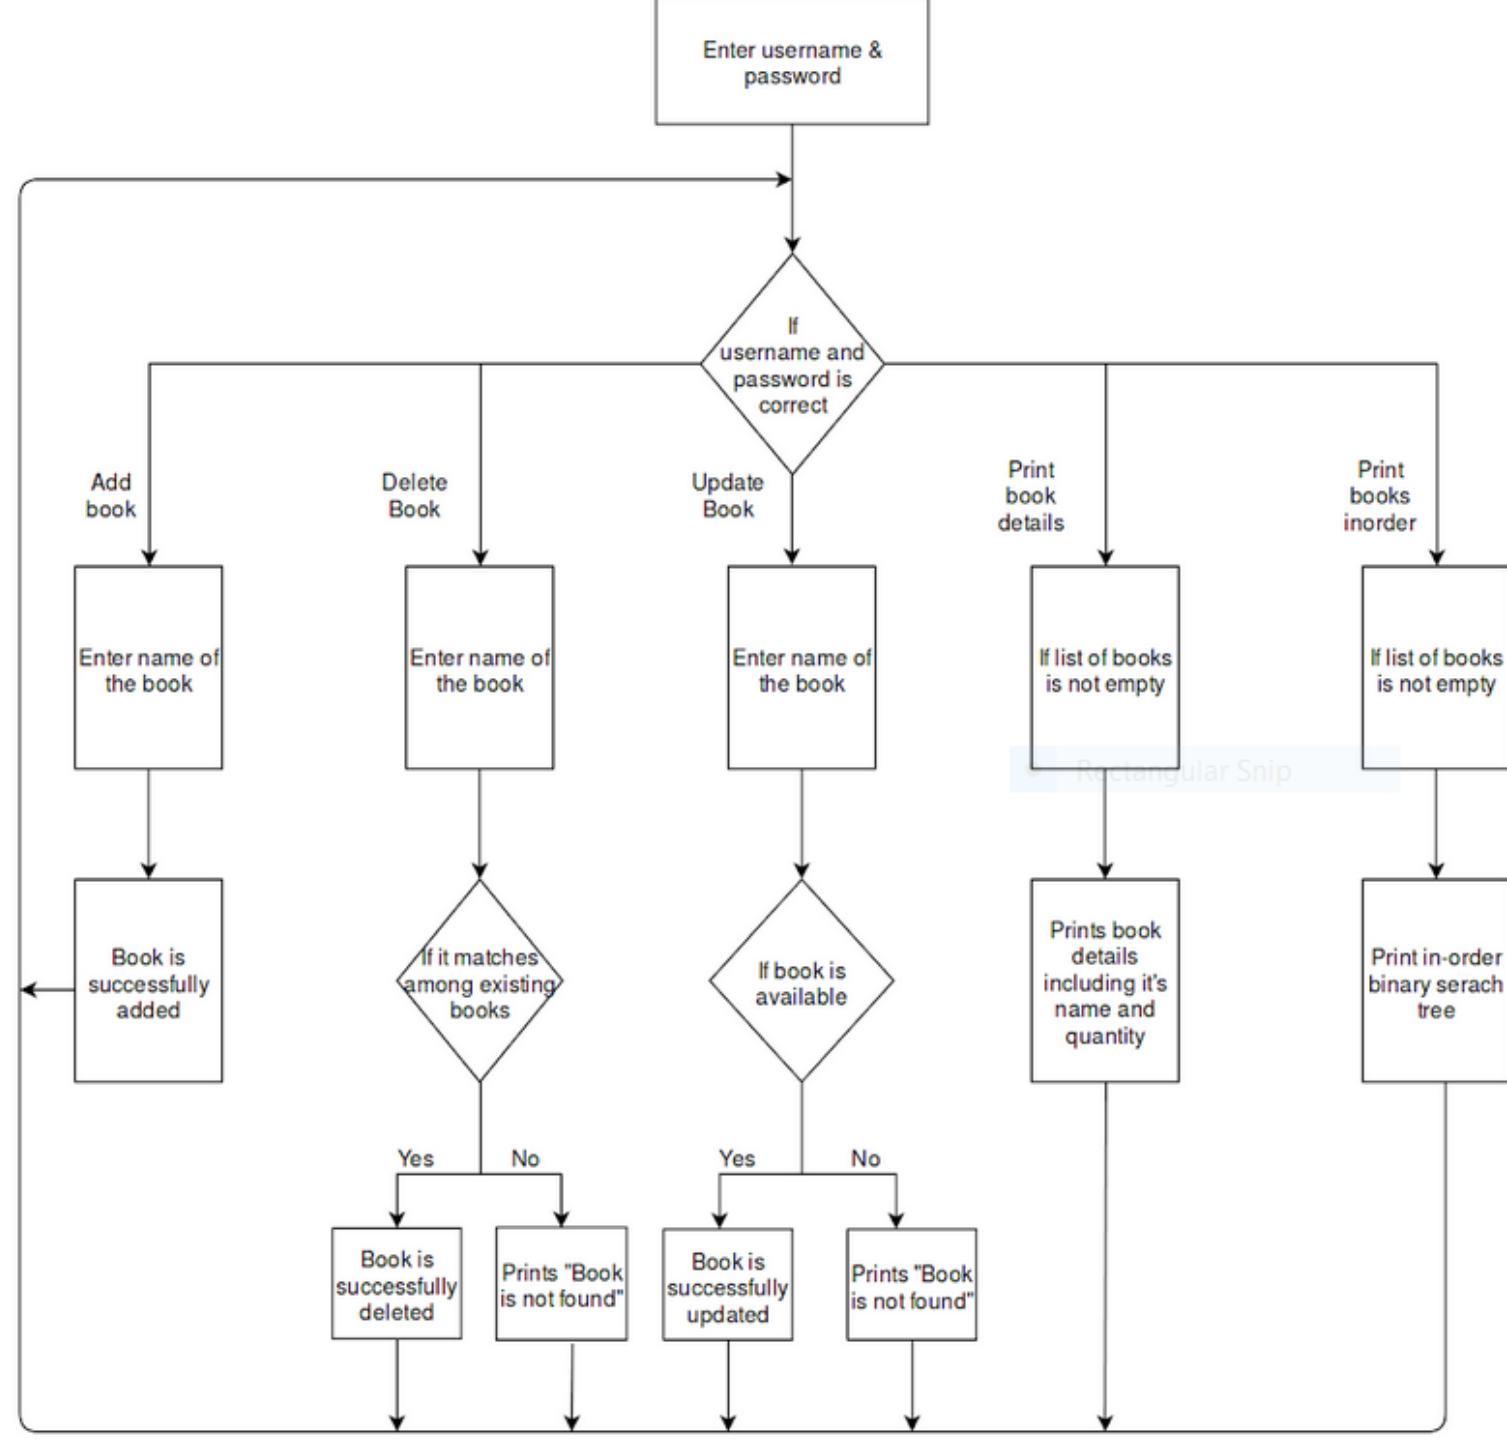

Data Structures used

- **Binary Search Tree:** Searching operation performs an in-order traversal on the created binary search tree to get the elements in sorted order.
- **Hash-Map:** Unique keys are generated using hash map and assigned to every book to avoid duplication of keys.
- **2-D array:** store the record of each book where rows indicate unique value for particular book which hash-map returns and columns indicate total quantity of books and available quantity of books.
